AB - J51136618 Tartaric acids are prep'd. by reacting maleic acid and H₂O₂ to obtain cis-epoxysuccinic acid. The cis-epoxysuccinic acid is hydrolysed in the presence of an enzyme (e.g. Nocardia tartaricans nov. sp., etc.) at 20-60 degrees C, pH 5-10 (pref. 6-9) to obtain the desired tartaric acid (generally present as a 2 sodium salt). Calcium maleate or a cpd. capable of forming calcium maleate (e.g., maleic anhydride and calcium hydroxide, etc.) is then added to the reaction mixt. at a pH 6.5-9 at >=100 degrees C to react with the tartaric acid to ppte. calcium tartrate. The mother liquor after sepg. the calcium tartrate, is recycled to the epoxidation step.

- Since the mother liquor after removal of the calcium tartrate can be recycled within the reaction system without discharging, the reaction can be conducted in a closed system.
